Introduction

In this paper, we will see how to develop a database, from modeling to its implementation in MySQL using SQL.

We have chosen the tourism industry, specifically a travel agency. We began by creating an entity-relationship model in the Dia program, where we defined the rules for our business model.

To convert the entity-relationship model to a relational model, we explored some online modeling alternatives, such as Vertabelo, which offers export options for different database engines and is free for students.

Once both models were designed, we found a website (mockaroo) that helped us generate a database with the previously created attributes. In addition to using this tool, we also generated random data using rules in Excel.

Finally, we used SQL to create the tables and insert the information into MySQL. We tested the queries using MySQL and RStudio (attached as appendices).

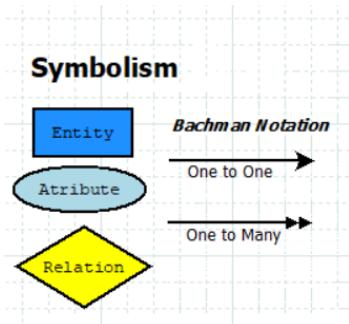

1.- Entity-Relationship Model

We used the "Dia" program to diagram the Entity-Relationship model using Bachman notation.

To create our Travel Agency, we started by defining the Entities and their attributes:

- **Client:** We defined its attributes as Name, Surname, Gender, Email, Mobile, Year of Birth, and finally Client ID, which would serve as the Primary Key.
- **Package:** It would have its own identifying code as the Primary Key, along with other attributes like Destination, Transportation, and Accommodation.
- **Reservation:** Like the Package Entity, it would have a Primary Key attribute to identify it, along with Price, Date, and Number of People.

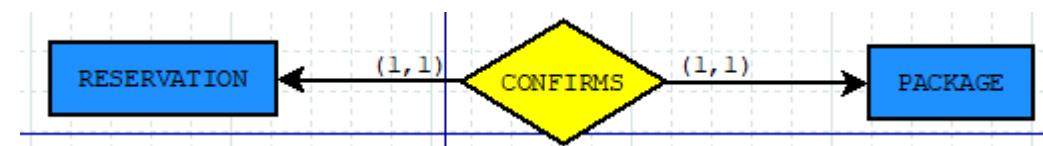

Rules and Conditions:

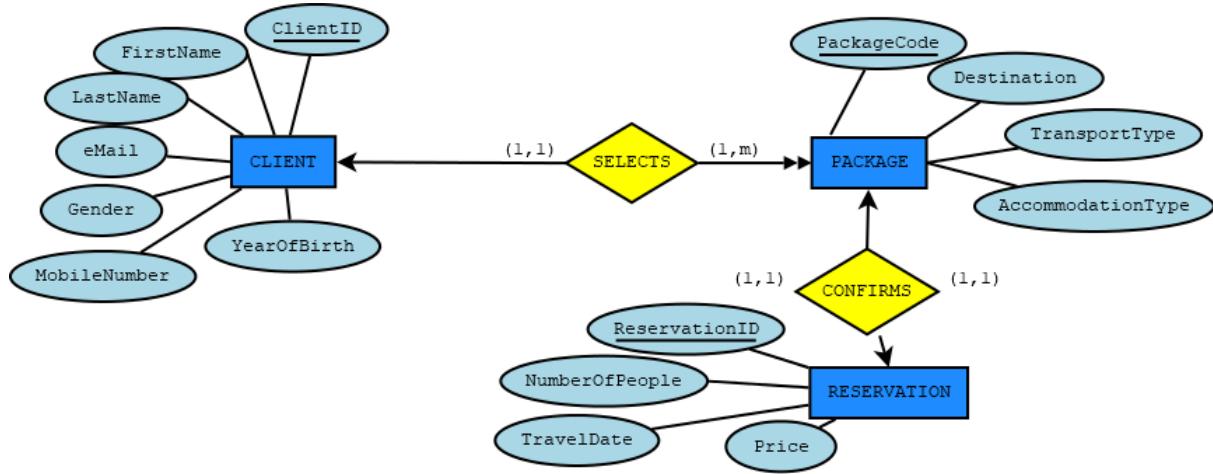

We defined that the Client Entity would be related to the Package Entity, where a client could purchase many packages, but each package would be associated with only one client.

The Package Entity and the Reservation Entity would be related to each other with a one-to-one cardinality.

2.- Relational Model

To create the Relational Model, we decided to use 'Vertabelo', an online database modeler that uses Information Engineering Notation (Cartmell, 2019) to represent a relationship, allowing each attribute to be displayed with its data type.

Rules and Conditions:

- **Client:**

1. ID(PK), ID: We decided to use the passport or ID of each person. While passports generally consist of 9 digits, we set the field to have 15 spaces to accommodate people who might want to use their national ID
2. Name, Surname, and Email: We used "nvarchar" because we believe it's important to take advantage of its Unicode character property, as this is a travel agency with an international outlook, even though this data type takes twice as much storage space (2 bytes) as "varchar" (<https://learn.microsoft.com>, 2022).
3. Gender, Mobile, and Year of Birth, are nullable variables,—they can be filled

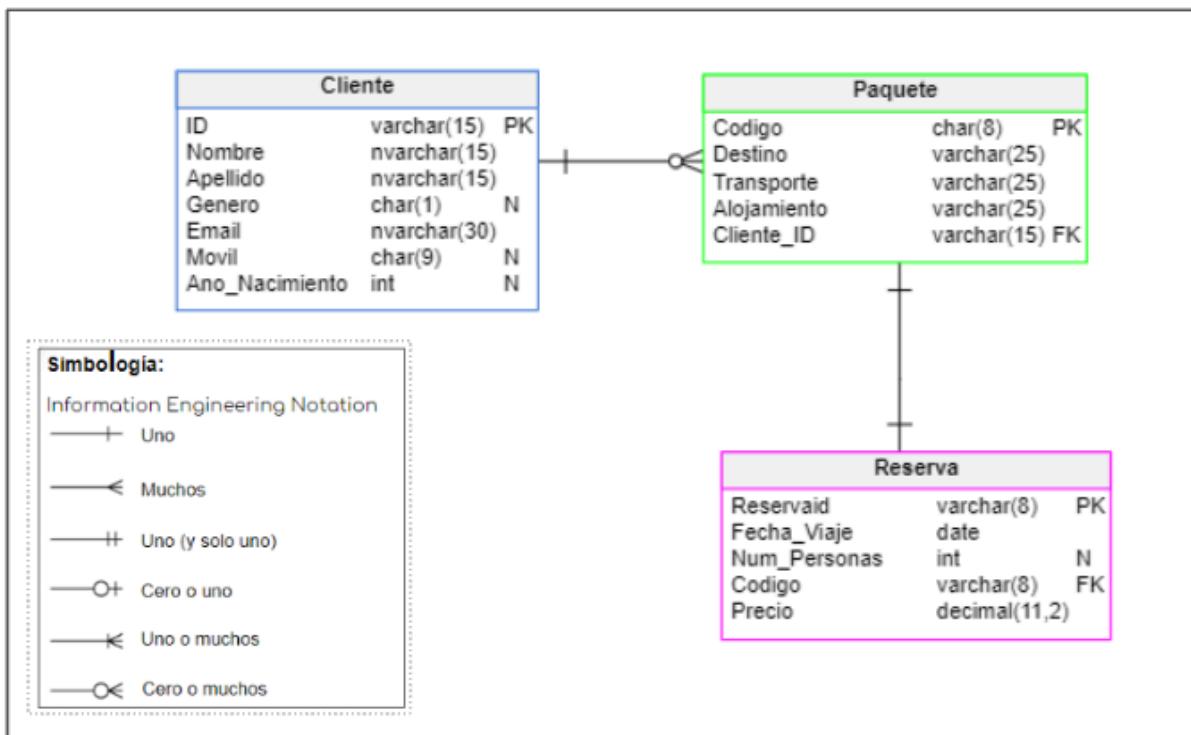

in or left blank by the client. Gender is a "char" that accepts only one character, Mobile is a "varchar" with nine spaces, and Year of Birth, which we decided on, is a "SmallInt." However, in Vertabelo, it's shown as "Int" because the platform doesn't offer a "SmallInt" option.

- **Package:**

1. ID_Package (PK) doesn't require more than an "char" with 8 spaces.
2. Destination, TransportationType, and AccommodationType were created as "nvarchar" with a capacity of 25 spaces.

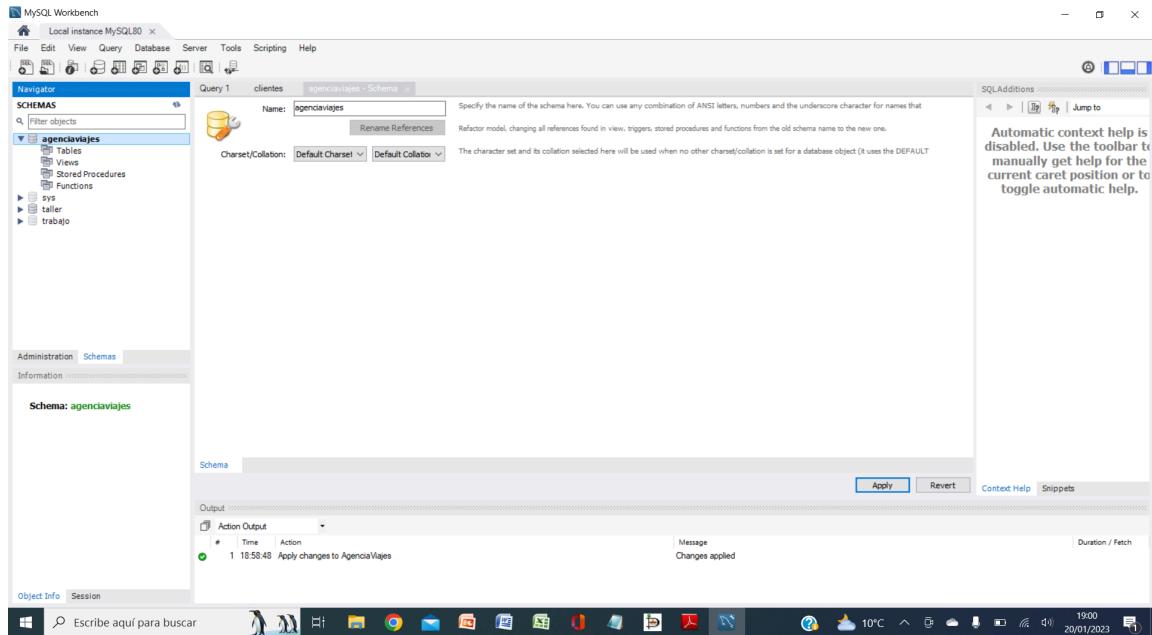

- **Reserva:**

1. Reservaid(PK), "Varchar" with 8 spaces
2. TravelDate, Assigned as a "Date" type.
3. NumberofPeople, "Int" with 6 spaces, which will be nullable.
4. Price: We used "Decimal" instead of "Float" because the former is more precise, and we're dealing with money. (Skov, 2009)

3.- SQL Sequences in a DBMS - Referential Integrity Rules and/or Business Rules

In this section, we discuss the implementation of our tables using the MySQL database management system, as well as the description of our various integrity rules. First, we'll create our database, which we'll call agenciaciajajes:

We add three tables in which we will load our data, which we describe as follows:

CLIENTE

| Column Name | Meaning | Data Type | NULLS allowed |
|--------------|---------------------------|---------------|---------------|
| ClientID | Identity document | CHAR(15) | N |
| FirstName | First Name | NVARCHAR (15) | N |
| LastName | Last Name | NVARCHAR (15) | N |
| Email | email address | NVARCHAR (30) | N |
| Gender | Gender (M male, F female) | CHAR (1) | Y |
| MobileNumber | Mobile Number | VARCHAR (9) | Y |
| YearOfBirth | Year Of Birth | SMALLINT | Y |

PAQUETE

| Column Name | Meaning | Data Type | NULLS allowed |
|-------------|---------|-----------|---------------|
| | | | |

| | | | |
|-------------------|--------------------|--------------|---|
| PackageCode | Package Code | CHAR (8) | N |
| Destination | Destination | VARCHAR (25) | N |
| TransportType | Transport Type | VARCHAR (25) | Y |
| AccommodationType | Accommodation Type | VARCHAR (25) | Y |
| ClientID | Client ID | VARCHAR (15) | N |

RESERVA

| Column Name | Meaning | Data Type | NULLS allowed |
|----------------|-------------------|----------------|---------------|
| Reservaid | Reserva Id | CHAR (8) | N |
| NumberOfPeople | Number Of People | SMALLINT | Y |
| TravelDate | Travel Date | DATE | N |
| Price | price | DECIMAL (11,2) | N |
| ClientID | Identity document | NVARCHAR (15) | N |

- Primary Key Integrity Rule

The primary key integrity rule is a constraint in a database that ensures each row in a table has a unique and non-null value in the column or set of columns forming the primary key. This means that no row can have an empty or duplicate value in the primary key column.

The primary key is a unique identifier for each row in a table and is used to relate tables to each other.

For example, in our database, we have 3 tables with a column that will be the primary key: in the Clients table, we have "ID", in the Package table, we have "Code", and in the Reservation table, we have "ReservationID". The primary key integrity rules apply automatically when creating a table with a specified primary key, ensuring that the data in the table is accurate.

- **Foreign Key Integrity Rule**

The foreign key is used to establish a relationship between two tables. For example, in our Clients table, we have a primary key called "ID", and in our Package table, we have a foreign key "ID", establishing a relationship between each package and a specific client.

- Business Rules

Business rules define the guidelines that determine an organization's business activities, but within our entity-relationship diagram, these rules will set our attributes, relationships, and constraints on our data. For example, one of our business rules is that our clients can have more than one package associated with them, as long as each package has an associated reservation. Another example is that all our clients must have Madrid as their origin, regardless of their destination.

4.- Data Loading

We will manually insert a record into the Clients table with the following SQL statement:

```
insert into clientes values ('30694573S', 'Odell', 'Sabine',  
'osabine0@stumbleupon.com', 'M', '663191383', '1959')
```

After executing this statement, we query the Clients table and get this record::

The screenshot shows the MySQL Workbench interface. In the left sidebar, under the 'Schemas' section, the 'agenciacvajes' schema is selected, and the 'clients' table is shown. The table has columns: id, nombre, apellido, eMail, genero, movil, and anonac. A single row is displayed in the result grid:

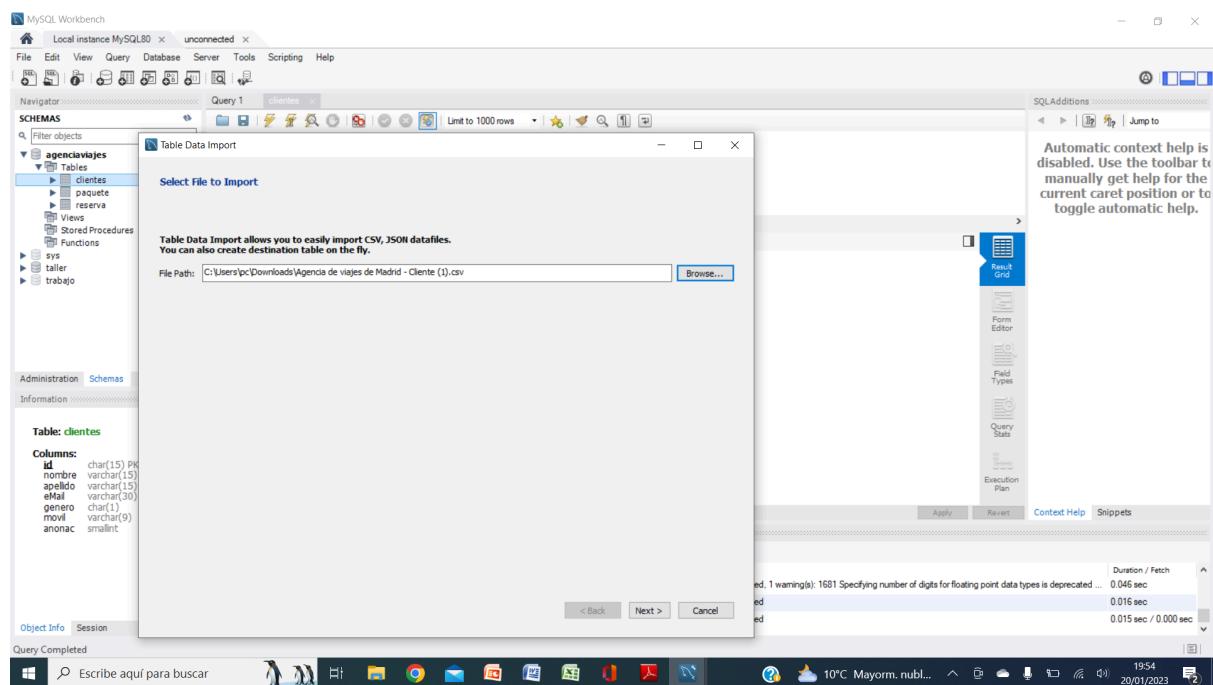

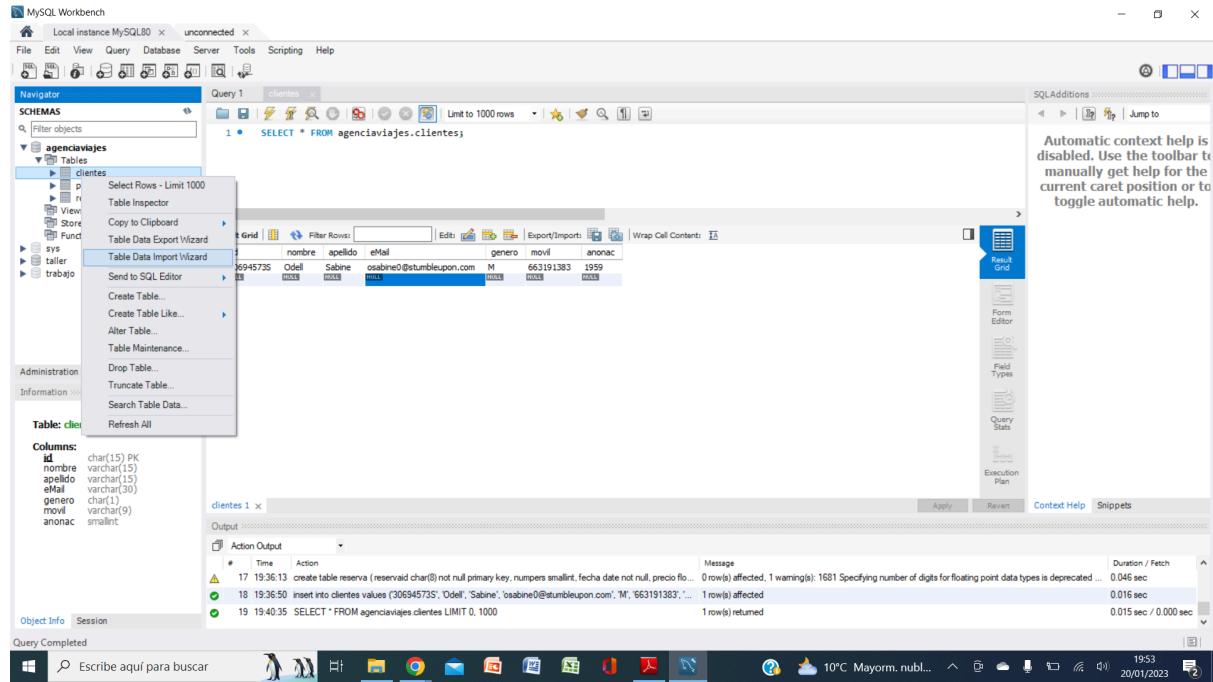

| id | nombre | apellido | eMail | genero | movil | anonac |
|-----------|--------|----------|--------------------------|--------|-----------|--------|
| 30694573S | Odell | Sabine | osabine0@stumbleupon.com | M | 663191383 | 1959 |

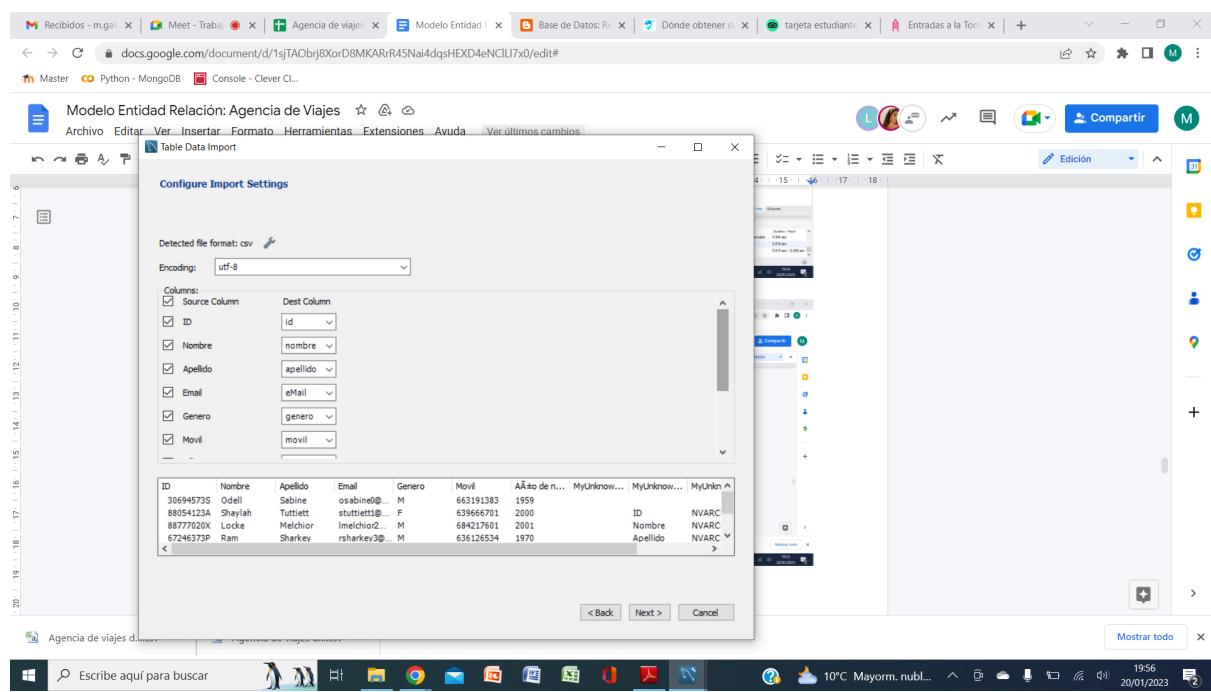

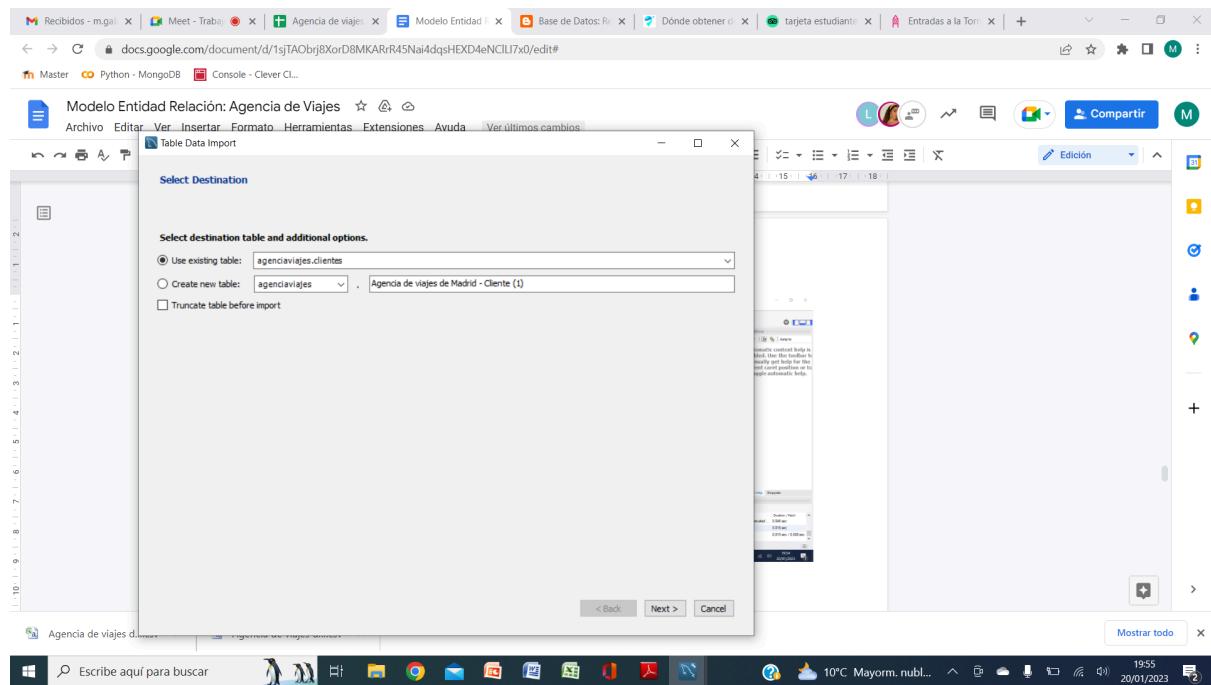

Below the result grid, the 'Action Output' pane shows the execution history:

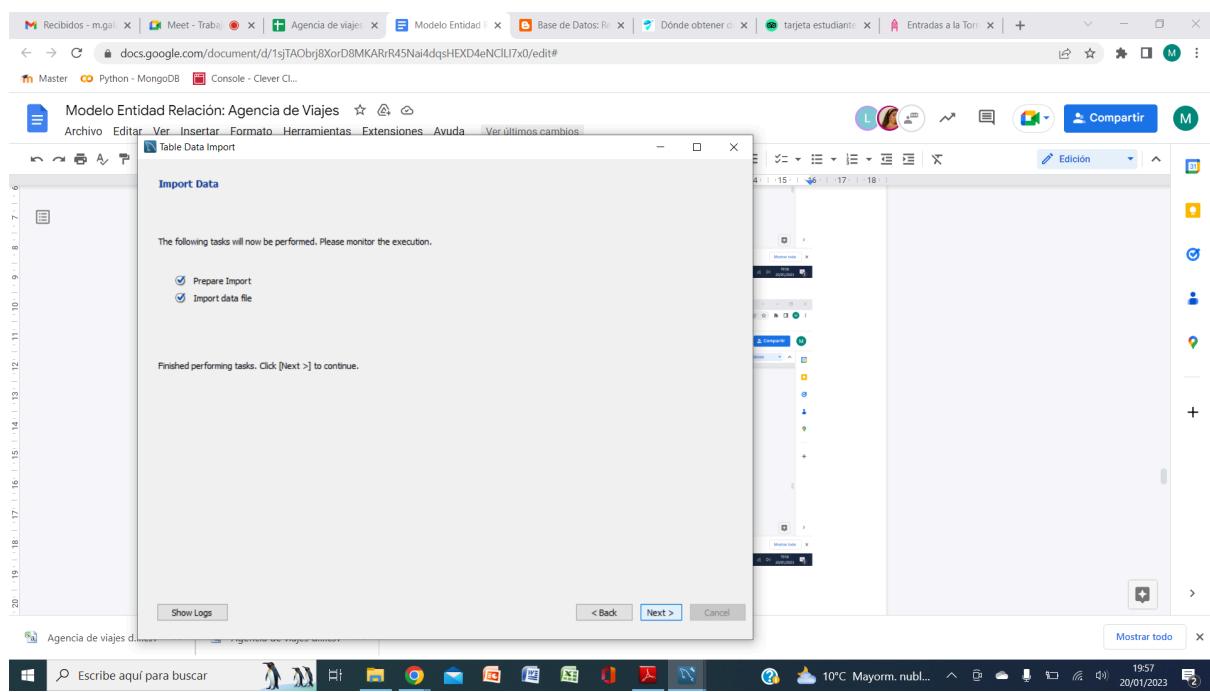

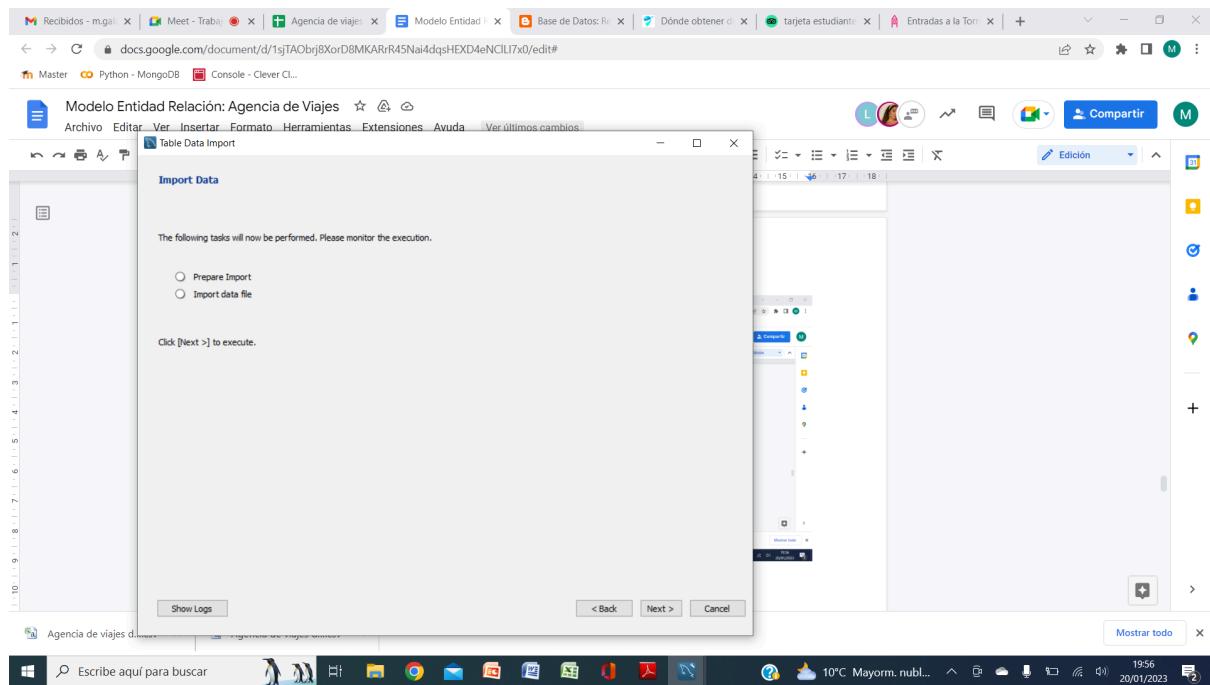

- 17 19:36:13 create table reserva (reserved char(8) not null primary key, numeros smallint, fecha date not null, precio float); 0 row(s) affected, 1 warning(s): 1681 Specifying number of digits for floating point data types is deprecated ... 0.046 sec
- 18 19:36:50 insert into clientes values ('30694573S', 'Odell', 'Sabine', 'osabine0@stumbleupon.com', 'M', '663191383', '1959'); 1 row(s) affected 0.016 sec
- 19 19:40:35 SELECT * FROM agenciacvajes clientes LIMIT 0, 1000; 1 row(s) returned 0.015 sec / 0.000 sec

To optimize data loading, and knowing how to do it manually, for the rest of the data, we will use bulk imports through CSV file imports. We start with an Excel document in Google Drive with 3 sheets (one for Clients, one for Packages, and one for Reservations), where group members entered data, and we exported each sheet to a CSV file.

Bulk Import of Data into the Clients Table To import data into the Clients table, we select the table, right-click, and choose the 'Table Data Import Wizard' option. The following outlines the steps we took:

We verify that the data has been loaded correctly:

The screenshot shows the MySQL Workbench interface with the 'clients' table selected in the 'Query 1' tab. The table structure is as follows:

| | id | nombre | apellido | eMail | genero | movil | anonac |
|----|-----------|----------|------------|------------------------------|--------|-----------|--------|
| 1 | 03815869P | Noell | McClaymond | rnmclaymond2g@narod.ru | F | 680277215 | 1959 |

The 'Action Output' section shows the following log entries:

| Action | Time | Message | Duration / Fetch |
|---|-------------|--|-----------------------|
| PREPARE stmt | 24 19:57:06 | FROM INSERT INTO 'agenciasvijes'.'clientes' ('id','nombre','apellido','eMail','genero','m... | 0.000 sec |
| DEALLOCATE PREPARE stmt | 25 19:57:07 | | 0.000 sec |
| SELECT * FROM agenciasvijes clientes LIMIT 0,1000 | 26 19:57:37 | 99 row(s) returned | 0.000 sec / 0.000 sec |

We followed these same steps to load the data for the Package and Reservation tables.

5.- Queries

We propose the following queries to work with our database:

1. How many packages have been purchased by gender and reservation year?
2. List the different destinations chosen each year.
3. How many female clients aged 18 to 25 used the airplane as a means of transport?
4. What was the most commonly used means of transport for clients born in the 1960s?
5. How many trips were made in 2021 with a price under 1000 and where the reservation code is between MAD00010 and MAD00050?
6. Find the people who traveled in groups of 3 before 2022, paid more than 2000, and sort the price in descending order

Next, we proceed to develop each query and its result:

5.I.1.- How many packages have been purchased by gender and reservation year?

```
select genero, extract(year from fecha) as ano, count(*) from paquete a inner join reserva b  
on a.codigo = b.reservaid inner join clientes c on a.id = c.id group by genero, ano order by  
genero, ano
```

The screenshot shows the MySQL Workbench interface. The top menu bar includes File, Edit, View, Query, Database, Server, Tools, Scripting, Help, and a toolbar with various icons. The left sidebar is the Navigator, showing the schema 'agencaviaciones' with tables 'clientes', 'paquete', and 'reserva'. The main area is titled 'Consultas' and contains the SQL query. The results grid shows the following data:

| genero | ano | count(*) |
|--------|------|----------|
| F | 2020 | 16 |
| F | 2021 | 29 |
| F | 2022 | 12 |
| M | 2020 | 14 |
| M | 2021 | 18 |
| M | 2022 | 25 |
| M | 2023 | 4 |

5.I.2.-List the different destinations chosen each year.

```
select distinct destino, extract(year from fecha) as ano from paquete a inner join reserva b on  
a.codigo = b.reservaid group by destino, ano
```

```

```
select distinct transporte, count(*) from paquete a inner join clientes b on a.id = b.id where
anonac >= 1960 and anonac < 1970 group by transporte order by transporte
```

The screenshot shows the MySQL Workbench interface. In the 'Navigator' pane, under the 'agenciaviajes' schema, the 'paquete' table is selected. In the 'Consultas' tab, a query is written:

```

20 select distinct transporte, count(*) from paquete a inner join clientes b on a.id = b.id
21 where anonac >= 1960 and anonac < 1970
22 group by transporte
23 order by transporte
24

```

The 'Result Grid' shows the following data:

| transporte | count(*) |
|-------------------|----------|
| Avion | 23 |
| Coche de alquiler | 2 |
| Tren | 4 |

5.I.5.-How many trips were made in 2021 with a price under 1000 and where the reservation code is between MAD00010 and MAD00050?

```
select * from reserva where fecha >= '20210101' and fecha <= '20211231' and reservaid
between "MAD00010" and "MAD00050" and precio < 1000
```

The screenshot shows the MySQL Workbench interface. In the 'Navigator' pane, under the 'agenciaviajes' schema, the 'reserva' table is selected. In the 'Consultas' tab, a query is written:

```

24
25 select * from reserva where fecha >= '20210101' and fecha <= '20211231' and reservaid between "MAD00010" and "MAD00050"
26 and precio < 1000
27
28
29
30
31
32

```

The 'Result Grid' shows the following data:

| reservaid | numbers | fecha | precio | codigo |
|-----------|---------|------------|--------|----------|
| MAD00030 | 5 | 2021-01-31 | 509.00 | MAD00030 |
| MAD00033 | 1 | 2021-02-08 | 875.00 | MAD00033 |
| * | NULL | NULL | NULL | NULL |

5.I.6.-Find the people who traveled in groups of 3 before 2022, paid more than 2000, and sort the price in descending order.

```
select * from reserva where numbers = 3 and fecha < '20220101' and precio > 2000 order by
precio desc
```

The screenshot shows the MySQL Workbench interface. On the left, the Navigator pane displays the database schema for 'agenciaviajes'. It includes tables like 'clientes' and 'paquete', and their respective columns, indexes, foreign keys, and triggers. On the right, the 'Consultas*' tab is active, showing a query window with the following SQL code:

```

27
28     select * from reserva where numpers = 3 and fecha < '20220101' and precio > 2000 order by precio desc
30
31

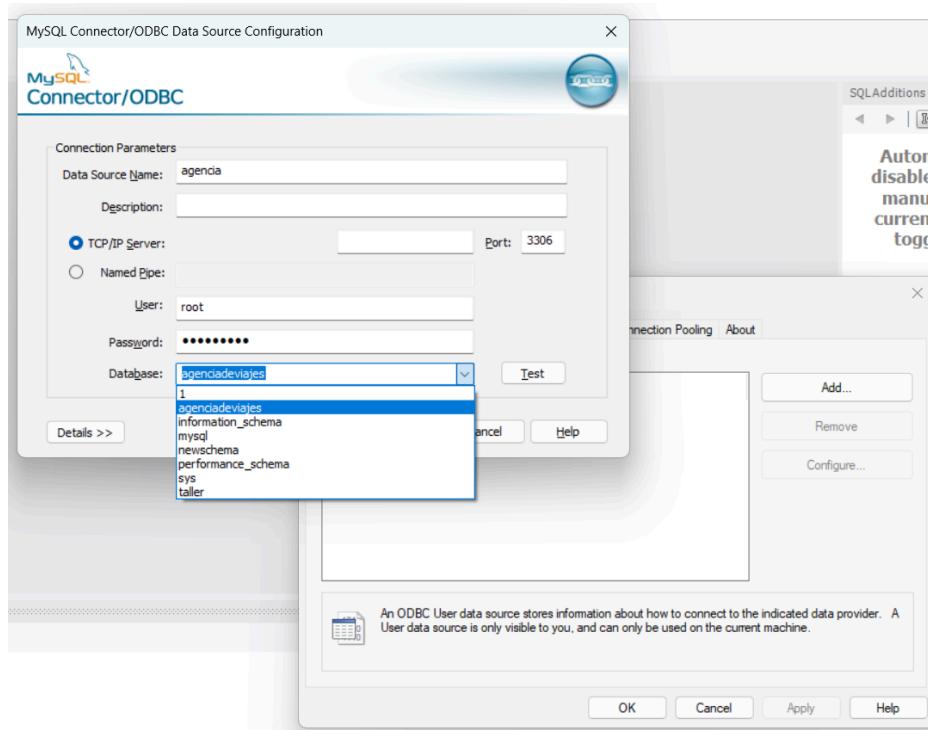

```

The result grid shows the output of the query, listing 15 rows of data from the 'reserva' table. The columns are 'reservaid', 'numpers', 'fecha', 'precio', and 'codigo'. The data includes various reservation details such as dates, prices, and codes.

| reservaid | numpers | fecha | precio | codigo |
|-----------|---------|------------|---------|----------|
| MAD00021 | 3 | 2020-10-25 | 5969.00 | MAD00021 |

| MAD00023 | 3 | 2020-12-01 | 2933.00 | MAD00023 |
| | | | | |

5.II.-Consultas vía RStudio.

Lo primero es descargar los paquetes SQLDF y RODBC en RStudio, y por medio de MySQL First, download the SQLDF and RODBC packages in RStudio, and then download the "ODBC Data Source" using the MySQL Installer. Next, establish the connection by filling in the information requested by the connector. For example, the password is the same as the one used for the MySQL engine, and you should locate the database you created. Then, execute the SQL queries in the same way as before.

6.- We have created a relational model. However, could you implement the above in another type of database?

Yes, it's possible to implement a relational model in another type of database. For example, you could implement it in a NoSQL database, like MongoDB or Cassandra, using a document-based or column-based schema, respectively. It could also be implemented in a graph database, like Neo4j, using nodes and relationships to represent the entities and relationships of the relational model. However, the relational model is better suited to relational databases and might require more effort to adapt it to a NoSQL database. It's important to remember that each type of database has its own advantages and disadvantages, so it's crucial to evaluate which is the best option for a specific application before making a decision.

7.- Analyze the Advantages and Disadvantages of Using a Non-Relational Database .

Based on the material provided in this course, the following are the various advantages and disadvantages of using a non-relational database.

Advantages

Data Volume: Non-relational databases can handle large amounts of data due to their distributed structure. They can store data of any type and allow data distribution across a cluster.

- Versatility: Non-relational databases offer flexibility in terms of scaling or changing storage methods without needing extra configurations. Queries are executed using JSON.
- Horizontal Scalability: They support distributed structures, enabling horizontal scaling. This means that if additional operational nodes are needed, they can be added, allowing for easier workload balancing. This is based on a "shared-nothing" architecture.
- Resource Availability: Non-relational databases do not require large amounts of resources, allowing for gradual growth as needed.
- Optimization: NoSQL databases use internal algorithms to rewrite queries submitted by users or applications, optimizing performance for all operations.
- Working without Schema: Working without a predefined schema offers flexibility and is suitable for handling semi-structured data:
- Flexibility: It's often more useful to store raw data without a strict schema. With a flexible schema, there's less work to be done upfront. Agile environments might require constant schema changes based on evolving requirements.
- Handling Semi-Structured Data: Non-relational databases are better suited for processing semi-structured or unstructured data.

Disadvantages

- Atomicity. Without this feature, we won't find consistent information.
- Software Documentation. Since this is a relatively new database, some operations are limited, sometimes requiring advanced knowledge of the tools and the people who develop this software.
- Language Standards. We didn't find a predetermined language for all possible NoSQL solutions.
- GUI (Graphical User Interface) Tools. A graphical interface isn't available; access is via the console, requiring extensive knowledge of the commands for maintenance.
- Similar to the advantages of not using a schema, we also found some disadvantages:
 - Absence of metadata, which is often required for analysis tools.
 - Implicit Schema. A schema must be created by the program from which we access the database, and this schema will only be defined within that application. However, this gives rise to other problems: the same database being accessed from different applications (generating different schemas) and our information undergoing changes that will be reflected in the programs.

Conclusion

We can conclude that DBMSs are a useful tool for any business, allowing various automated queries when needed. They enable the establishment of rules to optimally link and manage different tables and can be used with software like DBeaver, which helps improve import/export processes and syntax management. In this case, using MySQL, we found it to be a powerful and easy-to-use tool that allows data storage, retrieval, and manipulation. los datos.
